Abstract

Background: Recovery after stroke correlates with non-active (stunned) brain regions, which may persist for years. The current study aimed to evaluate whether increasing the level of dissolved oxygen by Hyperbaric Oxygen Therapy (HBOT) could activate neuroplasticity in patients with chronic neurologic deficiencies due to stroke.

Methods and Findings: A prospective, randomized, controlled trial including 74 patients (15 were excluded). All participants suffered a stroke 6-36 months prior to inclusion and had at least one motor dysfunction. After inclusion, patients were randomly assigned to "treated" or "cross" groups. Brain activity was assessed by SPECT imaging; neurologic functions were evaluated by NIHSS, ADL, and life quality. Patients in the treated group were evaluated twice: at baseline and after 40 HBOT sessions. Patients in the cross group were evaluated three times: at baseline, after a 2-month control period of no treatment, and after subsequent 2-months of 40 HBOT sessions. HBOT protocol: Two months of 40 sessions (5 days/week), 90 minutes each, 100% oxygen at 2 ATA. We found that the neurologic functions and life quality of all patients in both groups were significantly improved following the HBOT sessions while no improvement was found during the control period of the patients in the cross group. Results of SPECT imaging were well correlated with clinical improvement. Elevated brain activity was detected mostly in regions of live cells (as confirmed by CT) with low activity (based on SPECT) - regions of noticeable discrepancy between anatomy and physiology.

Conclusions: The results indicate that HBOT can lead to significant neurological improvements in post stroke patients even at chronic late stages. The observed clinical improvements imply that neuroplasticity can still be activated long after damage onset in regions where there is a brain SPECT/CT (anatomy/physiology) mismatch.

The role of hyperbaric oxygen therapy (HBOT) in the treatment of acute ischemic stroke is controversial. This prospective study assessed the efficacy and safety of HBOT as adjuvant treatment on 46 acute ischemic stroke in patients who did not receive thrombolytic therapy. The HBOT group (n = 16) received conventional medical treatment with 10 sessions of adjunctive HBOT within 3–5 days after stroke onset, while the control group (n = 30) received the same treatment but without HBOT. Early (second week after onset) and late (one month after onset) outcomes (National Institutes of Health Stroke Scale, NIHSS scores) and efficacy (changes of NIHSS scores) of HBOT were evaluated. The baseline clinical characteristics were similar in both groups. Both early and late outcomes of the HBOT group showed significant differences (P = 0.001). In the control group, there was only significant difference in early outcomes (P = 0.004). For early efficacy, there was no difference when comparing changes of NIHSS scores between the two groups (P = 0.14) but there was statistically significant difference when comparing changes of NIHSS scores at one month (P ≤ 0.004). The HBOT used in this study may be effective for patients with acute ischemic stroke and is a safe and harmless adjuvant treatment.

**REVERSE AGING: ATHEROSCLEROSIS-VASCULAR DEMENTIA & MCI**

---

**The Aging Brain**

Originally, doctors thought this degeneration was an unimportant part of aging.

But then research showed it is associated with cognitive decline and dementia.

So...

We recruited 5 adults who had white matter disease in their brains and we scanned their brains every week for 16 weeks to look for tiny, asymptomatic strokes.

What is the **CAUSE** of this white matter disease?

Clinical Effect of Free Radical Scavenger Combined with Hyperbaric Oxygen Therapy on Vascular Cognitive Impairment

Objective: To evaluate the clinical effect of free radical scavenger (FRS) combined with hyperbaric oxygen (HBO) therapy on vascular cognitive impairment (VCI).

Methods: A total of 164 patients with VCI were randomly divided into three treatment groups, i.e., HBO group, FRS group, and HBO/FRS combination group, and a control group. The clinical effects were evaluated based on the scores of mini-mental state examination (MMSE) and activity of daily living (ADL) scale before and after treatment.

Results: The HBO group, FRS group, and HBO/FRS combination group all showed significantly increased MMSE and ADL scores after treatment, better than the control group on the two measures. In addition, the above scores in the HBO/FRS combination group were higher than those in each of the HBO group and FRS group.

Conclusions: FRS combined HBO therapy can improve MMSE and ADL scores significantly in patients with VCI, showing better clinical effects, and holds promise for clinical application.
