The Effectiveness of Oral Non-Steroidal Anti-Inflammatories Versus Steroid Injections in Patients with Shoulder Pain

Darren Pledger PT, DPT, PA-S

Statement of the Problem

- The fact that shoulder pain is the third most common musculoskeletal complaint in primary care shows that clinicians must have an arsenal of quality interventions to treat this problem.
- The need for quality research and evidenced based guidelines are necessary to educate clinicians on their treatment options, the efficacy of these treatments, and their safety profiles.

Literature Review

- Ranelletta et al. found that pain was improved at all time points regardless of treatment group. However, relief was achieved faster in the corticosteroid injection group. This was statistically significant up to eight weeks (p<0.001), but lost significance (p=825) at 12 weeks as pain improved in the oral NSAID group.
- Shin and Lee (2013) found that all patients treated with corticosteroids, regardless of group, demonstrated statistically significant (p<0.05) faster pain relief and functional recovery up to 16 weeks compared to oral NSAIDs. Although corticosteroids were found to achieve faster results, at 24 weeks there was no statistical difference (p=0.670) in outcomes for all four groups.
- Sun, Chen, Li, Jiang, and Chen (2015) found that in terms of functional improvement, steroid injections showed superiority to oral NSAIDs (standard mean difference (SMD) 0.61; 95%CI, 0.50-0.74, p<0.00001).

Theme 1

1. In patients with shoulder pain, is oral non-steroidal anti-inflammatories or corticosteroid injections into the glenohumeral joint more effective in reducing shoulder pain?

2. What are the risks and side effects of oral non-steroidal anti-inflammatories and corticosteroid injections into the glenohumeral joint when used to treat shoulder pain?

Theme 2

- Nissen et al. (2016), Precision Trial, found statistically significant risk from no greater cardiovascular risk from celecoxib when compared to naproxen or ibuprofen.
- Castellsague et al. (2012), for individual NSAID use, they determined that ibuprofen was in the lowest range of pooled RRs while naproxen was associated with higher RR values depending on certain doses.
- Zhang, Doman, Bell, and Guthrie (2017) found that taking NSAIDs was associated in a 1.5-fold increase in the odds of developing AKI in the general population in people with (OR 1.63, 95%CI: 1.22-2.19, p=0.009) and without CKD (OR 1.73 95%CI: 1.44-2.07, p<0.0001).
- Patrono (2016) determined that traditional NSAIDs and coxibs increased the risk of major vascular events by 40% with the exception of naproxen.
- Rostom et al. (2011) found a clear advantage of selective COX-2s over nonselective NSAIDs on gastrointestinal safety with fewer gastrointestinal ulcers (RR 0.26, 95%CI: 0.23-0.30) and fewer complications from ulcers (RR 0.39, 95%CI: 0.31-0.50).

Discussion

- Many of the studies comparing corticosteroids to oral NSAIDs yielded similar results (Berry et al., 1989; Deghan et al., 2013; Petri et al., 1987; Ranelletta et al., 2016; Sun et al., 2015).
- There is a risk for upper gastrointestinal complications from corticosteroids. The COLLAB study, a clinical trial comparing cromolyn, physiotherapy, and injection and oral anti-inflammatory therapy in shoulder surgery, found no superiority in either treatment (Garcia Rodriquez & Barreales, 2007, Adebajo et al., 2013; Ranelletta et al., 2016; Sun & Lee, 2013).
- Many of the studies in theme one had very small sample sizes.
- There is a small amount of literature directly comparing oral NSAIDs to corticosteroid injection.
- A wide range of shoulder conditions were studied in theme one lacking consistency.
- Many studies in theme one were dated.

- There is a risk for upper gastrointestinal complications (Castellsague et al., 2012; Chang et al., 2011; García Rodríguez & Barreales Tolosa, 2007; Rostom et al., 2011; Nissen et al., 2016).
- Non-selective oral NSAIDs pose the greatest risk followed by selective oral NSAIDs. Although selective oral NSAIDs were found to decrease the risk of upper gastrointestinal complications, they found that taking aspirins with selective NSAIDs virtually cancels out their gastroprotective effect (García Rodríguez & Barreales Tolosa, 2007).
- The studies showed an increase in cardiovascular risk to a varying degree of all NSAIDs (Chang et al., 2011; Nissen et al., 2016; Patrono, 2016).
- All NSAIDs pose a risk to the kidney and AKI is possible in healthy populations as well as the elderly (Chou et al., 2016; Zhang et al., 2017).

Conclusion

- Both oral NSAIDs and corticosteroid injection are effective in reducing shoulder pain.
- Both treatments can treat a wide range of conditions.
- Both are superior to placebo while neither is superior to the other, thus the decision on what treatment to use should be based on an individuals comorbidities and risk factors.
- There are side effects associated with both treatments.
