But then what?
So, if someone has a concussion, how is that treated?

**June 21, 2018**

- **Dr. Lara DePadilla**, **Behavioral Scientist, Centers for Disease Control and Prevention**

  - “Well, as I’ve kind of alluded to, there is no one size fits all approach to treating concussion. Instead, healthcare providers can create a tailored return to activity plan that makes sense with a person’s individual symptoms. This could include short-term changes to a person’s daily activities, such as wearing sunglasses if they’re having light sensitivity, or maybe allowing for breaks at school if they’re feeling more slowed down than usual. But as they feel better, they can start to remove these changes and use their symptoms as a guide for how quickly to return to normal activities.”
1 in 5 Teens Reports a Concussion

“About 20 percent of teens said they have been diagnosed with at least one concussion. And nearly 6 percent said they've been diagnosed with more than one, according to a research letter published Tuesday in the Journal of the American Medical Association.”

The Management of Traumatic Brain Injury in Children: Opportunities for Action

2018
Recovery Time

mTBI

Mild TBI
Common symptoms of mTBI include headaches, dizziness, and problems with thinking/memory, changes in moods/emotions, and sleep difficulties (Table 1). Symptoms usually develop immediately, but they can also develop over a few days after injury. Longitudinal studies suggest that most children with mTBI recover from the initial symptoms within 6 weeks after injury, with 30-60% having persistent symptoms at one month post-injury, 10% at three months post-injury, and less than 5% at one year post-injury. Although children can recover quickly from the initial symptoms, little information is available about the long-term outcomes of single or multiple mTBIs in children, particularly among those who experience an mTBI at a young age. In addition to changes in thinking and memory, children can also experience changes in their motor systems, such as balance and postural instability, and these can affect the motor performance that is critical for a return to physical activities.
Consequences

• “….social isolation…..harmful effects on their well-being.”

Return to activity
Although return-to-play guidelines for sports have been devised for mTBI, similar consensus guidelines have not been developed for return to other recreational and physical activities outside of organized sports.

Following TBI, children are at risk for increased social isolation and reduced participation in activities outside of the school setting, and this can have harmful effects on their well-being.

While there may be awareness of these risks among those who care for children, there is a lack of guidance as to how to minimize these risks. Additionally, neither consensus nor evidence-based guidelines for return to activities after moderate and severe TBI exist.

Transition to adulthood for children with TBI
As children reach adulthood, the transition from pediatric to adult medical care providers is a particular area of clinical concern.90 Research has demonstrated that access to (and use of) healthcare services declines significantly as adolescents transition to adult care, resulting in worse health outcomes in adolescents with identified health conditions.91 As in the public school system, only children enrolled in special education when they enter high school...
INCIDENCE

Traumatic brain injury in children represents a significant public health burden in the United States.

A traumatic brain injury disrupts the normal function of the brain, and can be caused by a bump, blow, or jolt to the head, or a penetrating head injury.

In 2013, there were approximately 640,000 TBI-related emergency department (ED) visits, 18,000 TBI-related hospitalizations, and 1,500 TBI-related deaths among children 14 years of age and younger. The leading cause of TBI-related ED visits, hospitalizations, and deaths was motor vehicle crashes and falls. Sports and recreation-related TBIs are a leading cause of TBI-related ED visits among children and teens with an estimated 320,000 occurring in 2012.

Children with TBI can present to a number of clinical locations: the ED, urgent care clinics, primary care, concussion/sports medicine clinics, or other specialty clinics. In addition, some do not seek or receive medical care. Recent research examining the point of entry in a large healthcare network found that among pediatric patients with mild TBI (mTBI), 82% visited a primary care, ED, or specialty care, and 12% visited ED only. This information suggests that incidence estimates of pediatric TBI based solely on ED visit data are significant undercounts, likely missing those with mTBIs seen at lower levels of care, in addition to those with mTBIs who don’t seek care at all. Because of these gaps in TBI surveillance, researchers have estimated the true burden of pediatric TBI to be much higher. mTBI accounts for 70-90% of ED visits.
School outcomes
A child’s daily life is centered on school, social participation, and extracurricular activities. A TBI of any severity can negatively affect a child’s future ability to learn and perform in school. Children with a moderate-to-severe TBI earn worse grades, show higher rates of grade retention, and receive more special education services than their uninjured peers. Students with a mild injury typically recover within a few weeks, and most of them return to their pre-injury classrooms. However, in a large study following children younger than 18 years of age, 14% of children who experienced an mTBI needed educational support services at school twelve months later. Furthermore, educational needs can emerge over time as school demands increase, especially among children injured at a young age. In a cross-sectional study, children with complicated mild and moderate TBI needed more school supports 6 years post-injury than they did 2 years post-injury. Recent studies examining adults with a history of mTBI also report an increased risk for lower educational attainment, particularly among those who sustain multiple TBIs.

TREAT a Concussion

Currently, no “TREATment.”

We have concussion “management.”

2018
In 2017, “REST” Is the best we’ve got?
Hyperbaric Oxygen just makes sense

Jill Barker: Exercise or rest after a concussion?

When it comes to concussions, rest is often recommended as the first line of treatment. But in the last couple of years, staying sedentary while waiting for a concussion to heal is no longer a given. Instead, physical activity is now considered a viable part of an overall treatment plan — especially in those crucial first few days post concussion.

It turns out that the science behind rest after receiving a blow to the head isn’t as strong as previously thought. There’s even discussion suggesting it may be more harmful than helpful, leading to increased risk of lethargy, anxiety and depression, especially among the active set for whom exercise is a vital part of their lifestyle.

The support behind the idea that exercise can help heal concussions is the result of a growing number of studies posting positive results when exercise is introduced sooner rather than later during post-concussion care. One of the most recent studies, performed by a team out of the Children’s Hospital of Eastern Ontario Research Institute, reported that “resumption of physical activity within seven days post concussion was associated with a lower risk of Persistent Post Concussion Syndrome as compared to no physical activity.”

“Preliminary studies in concussed adolescents found that participants engaging in moderate levels of activity reported lower symptom levels and superior neurocognitive performance compared to those with physical rest,” stated the researchers.

No one is ready to go on record to explain why exercise is so beneficial, though there has been plenty of suggestion that the boost in oxygen flow associated with exercise allows the brain to heal quicker as compared to the more sluggish cerebral blood flow associated with sedentary behaviour.

- Diagnosed in ER with a concussion
- Pediatrician recommended HBO
- 2:00 Saturday (less 24 hours) Tx

Wow, I was messed up!

“Are you better than what you thought you needed to be?”
2. Concussed athletes do not appreciate full extent of their injury

The damaged brain just doesn’t self-report very well

Danger of returning too early
Father emailed me

“(Patient) resumed playing after sitting for (2) games and did not have any impairment from the original concussion. School and social activities were back on par after a week. Currently, he is enrolled at (university) as a student-athlete. He is likely to red shirt this season to get his body prepared for the rigors of playing in the Big Ten.”

[He did not miss a single day of school.]
3. Can we stop full extent of concussion?

What if we start treatment before full progression of concussion?
Retrograde amnesia
Risk factor for prolonged recovery

• 12 year old male could not remember events 1 hour prior to fall

• HBO less 3 hours after injury

• 5 treatments

• Back in school 1 week after (Monday)
• No issues now 3 months out
Retrograde amnesia

• 12 year old male hockey player, boarded
• Appeared to have shoulder injury---off ice, dazed

• Coach sent him to locker room
• Father got him out of his uniform, drove home

• 45 minutes later, took ice pack off his head
  “What happened?”
Concussion mitigated?

- 1st HBO five hours after injury
- Was back in school by Tuesday, 3 days post-injury
- Total of 6 treatments
- Worth noting, he had a previous concussion year prior
Prevent Concussion Progression

30 patients began treatment 1 day or less from injury
4. Can we decrease risk of subsequent concussions?

We have had 4 recurrent

“1 in 15 players with a concussion may have additional concussions in the same playing season”
Subsequent Concussions

*Time will tell*

- One of our “recurrent concussion” patients

  16 year old, straight A student, couldn’t read
  Post-concussive syndrome until 15 HBO July 2016

  Started playing lacrosse May 2017
  Returned twice less 24 hours after injury
  fear of another concussion

• Met January 14, 2018

• Less 6 months
  • Found and built out incredible space
  • 4 chambers
  • Room to grow
Visual Symptoms
69-82% of concussed patients

• Dr. David Biberdorf will test patients prior to treatment and immediately after HBO.

We will have OBJECTIVE EVIDENCE
Future:

- Protocol perfection
  - MRI pre-season
  - Eye studies

- Can we change the attitude of reporting a concussion

- Longer term follow up
  - Academic performance
  - Social/emotional
  - Subsequent concussions

- Cost-effective
Risk of suicide after a concussion

Michael Fralick MD BSCH, Deva Thiruchelvam MSc, Homer C. Tien MD MSc, Donald A. Redelmeier MD MS(HR)

CMAJ Podcasts: author interview at https://soundcloud.com/cmajpodcasts/150790-res

Abstract

Background: Head injuries have been associated with subsequent suicide among military personnel, but outcomes after a concussion in the community are uncertain. We assessed the long-term risk of suicide after concussions occurring on weekends or weekdays in the community.

Methods: We performed a longitudinal cohort analysis of adults with diagnosis of a concussion in Ontario, Canada, from Apr. 1, 1992, to Mar. 31, 2012 (a 20-yr period), excluding severe cases that resulted in hospital admission. The primary outcome was the long-term risk of suicide after a weekend or weekday concussion.

Results: We identified 235,110 patients with a concussion. Their mean age was 41 years, 52% were men, and most (86%) lived in an urban location. A total of 667 subsequent suicides occurred over a median follow-up of 9.3 years, equivalent to 31 deaths per 100,000 patients annually or 3 times the population norm. Weekend concussions were associated with a one-third further increased risk of suicide compared with weekday concussions (relative risk 1.36, 95% confidence interval 1.14-1.64). The increased risk applied regardless of patients’ demographic characteristics, was independent of past psychiatric conditions, became accentuated with time and exceeded the risk among military personnel. Half of these patients had visited a physician in the last week of life.

Interpretation: Adults with a diagnosis of concussion had an increased long-term risk of suicide, particularly after concussions on weekends. Greater attention to the long-term care of patients after a concussion in the community might save lives because deaths from suicide can be prevented.

Competing interests: None declared.
